## **Errors in Abdominal Radiology** Manuel Jr. Viamonte

There are many diagnostic imaging techniques for the radiological examination of the abdomen. Noninvasive methods include supine and upright views of the abdomen (sometimes fluoroscopy and decubitus films); posteroanterior (PA) views of the chest; contrast studies of the alimentary tract; ultrasonography (US), scintigraphy, computed tomography (CT), and magnetic resonance imaging (MRI). Biopsy under fluoroscopic control and angiography are invasive techniques. Most of the errors described in this book are related to faulty interpretation; others are due to improper technique. For example, a patient with acute abdominal pain secondary to a perforated hollow viscus may be studied only by supine and upright views of the abdomen that do not include the subdiaphragmatic regions. A complementary PA view of the chest or a left lateral decubitus film would, however, detect free air in the peritoneal cavity that the incomplete two-film study might have missed. Errors of technique are due to under- or overexposure, long examination times or an uncooperative patient (both of which can induce motion artifacts), improper processing, and failure to perform the proper standard noninvasive or invasive modalities for examining the hollow viscus and the solid organs of the alimentary tract. In order to visualize the diaphragm and the supra- and subdiaphragmatic spaces, frontal and lateral chest roentgenograms complement the standard views of the abdomen. Fluoroscopy is of great value in assessing diaphragmatic motion as well as being essential when contrast media are utilized.
